

#	Title / Summary	Steps to Reproduce	Expected vs Actual	Severity	Suspected Cause
1	Weak password accepted	Enter very weak password during signup	Expected: reject weak password. Actual: account created successfully	High	Missing password validation
2	Duplicate article submission	Double-click Publish button quickly	Expected: one article created. Actual: duplicate articles created	Medium	Submit button not disabled during API request
3	Session handling inconsistent	Stay idle after login and refresh later	Expected: clean session expiration. Actual: stale session behavior	High	Improper token/session handling
4	Poor invalid login error message	Enter wrong credentials	Expected: clear helpful message. Actual: vague error shown	Medium	Backend error not mapped properly
5	Accessibility issue with keyboard navigation	Navigate forms using keyboard only	Expected: visible focus indicators. Actual: difficult keyboard navigation	Low	Missing accessibility-focused UI states

Root Cause Analysis:

Problem: When a user clicks the Publish button, the frontend sends an API request but doesn't disable the button while waiting for a response, so clicking multiple times quickly sends several identical requests and creates duplicate articles in the database.

Root Cause: The frontend is missing state management — there's no loading state or button-disabling logic during async operations — and the backend has no safeguard to reject or deduplicate repeated requests.

Fix: Disable the Publish button immediately on the first click and re-enable it only after the request finishes, add a loading spinner for better user feedback, and implement idempotency or duplicate request validation on the backend as an extra layer of protection.
